

# Non-Negative Matrix Factorization

Clayton W. Schupp, Galvanize

Spring 2015

# NMF Overview

## What is NMF

- A group of algorithms that takes a large dimensional matrix and factors into 2 (or more) smaller dimensional matrices
- The matrices are all non-negative
  - Often inherent in the data being considered
  - Makes the resulting matrices easier to inspect and interpret
- This smaller dimension makes the matrices easier to store

## NMF Overview

Matrix  $V_{m \times n}$  where each entry  $v_{ij} \geq 0$

$$\underset{m \times r}{W} * \underset{r \times n}{H} = \underset{m \times n}{V}$$

also  $w_{ij} \geq 0$

$h_{ij} \geq 0$

$r$  is set by the user and can be substantially smaller than either  $(m, n)$

## NMF Overview

Matrix  $V_{m \times n}$  where each entry  $v_{ij} \geq 0$

$$\underset{m \times r}{W} * \underset{r \times n}{H} = \underset{m \times n}{V}$$

also  $w_{ij} \geq 0$

$h_{ij} \geq 0$

The columns of  $V$  are linear combinations of the columns of  $W$  weighted by the corresponding column in  $H$

$$v_i = W * h_i$$

where  $v_i$  and  $h_i$  are the  $i^{th}$  column vectors of  $V$  and  $H$  respectively

## Text Mining Example

- Let the input be  $V$  be the input matrix with 10000 rows and 500 columns
  - words are rows
  - documents are columns
- Assume we want to find 10 hidden features.  
Want to generate:
  - $W$  with 10000 rows and 10 columns
  - $H$  has 10 rows and 500 columns

# Document Clustering with NMF

500 documents  
10,000 words

$$V = W * H$$

$$\begin{array}{c} \text{documents} \\ \left[ \begin{array}{c} \\ \\ \\ \end{array} \right] \\ \text{words} \end{array} = \begin{array}{c} \text{latent factors} \\ \left[ \begin{array}{c} \\ \\ \\ \end{array} \right] \\ \text{words} \end{array} \times \begin{array}{c} \text{documents} \\ \left[ \begin{array}{c} \\ \\ \\ \end{array} \right] \\ \text{latent factors} \end{array}$$

# Document Clustering with NMF

Column in  $W$ :

- document archetype
- word's cell value establishes it's rank for that latent feature

# Document Clustering with NMF

Column in  $H$ :

- Original document
- Cell value is document's rank for that latent feature

# Document Clustering with NMF

Recall  $v_i = W * h_i$ , so  $v_i$ :

- is rebuilding a particular document
- linear combination of document archetypes weighted by how important they are

# Algorithm

Want to minimize RMSE

$$\text{Minimize } ||V - WH||^2 \text{ with respect to } W \text{ and } H \\ \text{subject to } W, H \geq 0$$

- Lee and Seung's multiplicative update rules
  - good compromise between speed and ease of implementation
- Additive update rules such as gradient descent
  - easiest to implement but convergence can be slow
  - convergence is sensitive to choice of step size

# Algorithm

Minimize  $\|V - WH\|^2$  with respect to  $W$  and  $H$   
 subject to  $W, H \geq 0$

Multiplicative Update Steps:

- Start with some random  $W$  and  $H$
- Repeatedly adjust  $W$  and  $H$  to make RMSE smaller

$$H_{a\mu} \leftarrow H_{a\mu} \frac{(W^T V)_{a\mu}}{(W^T WH)_{a\mu}} \qquad W_{ia} \leftarrow W_{ia} \frac{(VH^T)_{ia}}{(WHH^T)_{ia}}$$

- Stop when some threshold is met
